Hygienic Practices of Anesthetists in the United Kingdom

Gina Pugliese, RN, MS Martin S. Favero, PhD

Dr. el Mikatti and colleagues from Withington Hospital, United Kingdom, conducted a survey to assess hygienic precautions taken by anesthesiologists. Questionnaires were distributed to all 213 consultant anesthetists in the northwest region of the United Kingdom, with a response rate of 68%.

Face masks and gloves were always used by 35% and 15%, respectively; only 36% washed their hands between cases. A high proportion of anesthetists continue to administer anesthesia despite suffering from respiratory (94%), gastrointestinal (42.9%), or herpes simplex (32.6%) infections. The anesthetic breathing system was changed at the end of each day or following a high-risk case by 33% of the respondents, whereas just over 25%

changed it following a known infected case. Bacterial filters were used by 17% and changed after each case by 7%. The authors concluded that, although anesthetists are well aware of proper hygienic practices, their performance falls short of accepted recommendations.

Inactivation of Cryptosporidium parvum Oocyst

Gina Pugliese, RN, MS Martin S. Favero, PhD

Cryptosporidium parvum is a common cause of self-limited gastroenteritis in the normal host but severe disease cause in immunocompromised persons. Person-to-person transmission has been well documented in households, child-care centers, and hospitals. Because contaminated environmental surfaces and medical devices such as endoscopes may play a role in disease transmission, Barbee and coinvestigators from the University of North Carolina studied the susceptibility of C parvum to chemical agents commonly used for disinfection of medical devices, as well as the

efficacy of sterilization processes. Seven disinfectants were studied at their use dilution using a suspension test. Antimicrobial activity was assessed with the use of a cell infectivity assay.

All sterilization processes tested (steam, ethylene oxide, hydrogen peroxide gas plasma [Sterrad 100, Advanced Sterilization Products, Irvine, CA]), inactivated 3 logs or greater of *C parvum*. The only liquid disinfectant or sterilant able to inactivate greater than 3 logs of *C parvum* was 6% and 7.5% hydrogen peroxide. Agents that did not completely inactivate *C parvum* included hydrogen peroxide at lower concentrations or exposure times, peracetic acid, sodium hypochlorite, a pheno-

lic, a quaternary ammonium compound, 2% glutaraldehyde, and orthophthalaldehyde.

The authors concluded that most high-level disinfectants used on endoscopes have limited efficacy against *C parvum*. However, the infectivity of *C parvum* on dry surfaces decreases rapidly. Therefore, current cleaning and high-level disinfection guidelines are adequate to prevent nosocomial transmission of *C parvum* by means of endoscopes.
